Dear Dr Lederberg,

Thank you very much for the quick reply and the criticism with which I agree.

I am sorry to say that I did not make any further progress since then, as I had to prepare an exhibit for the Annual Meeting of the American TB Association. Only my exhibit staff went to Chicago, I did not get the U.S. visa.

You may have been surprised that after some successful transduction experiments I still seemed to stick to the idea of recombination in mycobacteria. However, at that time despite similarities there were also differences observable between the strains obtained by transduction and that special strain resembling "atypical" acid fast mycobacteria. While the transduced strains showed only S^+ and this also in a lower frequency, the R.E.1 strain had mixed hereditary characters suggesting the possibility of conjugation. - At present, it seems more probable that S^+ is transduced both if intact cells or a cell-free filtrate carries the genetic information. So, I should forget about conjugation, for a while at least and make it really more what I deal with is: transduction. I am afraid that we will face a big problem to get a unicellular organism in order to make single cell cultures.

I still hope to find somebody who works with it in one of the university departments.

I am very much interested on what you work now? How do you like your new place? Are you completely settled there? And is it like to what you expected? I wish much meet those in your new department and thank you once again

Sincerely yours
Stephen Julian
